What is a Breast Fine Needle Aspiration?

A Breast Fine Needle Aspiration (FNA) is a quick and simple procedure to perform, which removes some fluid or cells from a breast lesion or cyst (a lump, sore or swelling) with a fine needle similar to a blood sample needle. The sample of fluid or cells is smeared on a glass slide and sent to a pathology laboratory to be examined by a specialist doctor (a cytologist) under a microscope. An FNA is performed to help determine the nature or diagnosis of the lesion and to plan treatment if necessary.

Breast FNA may also be used to aspirate a cyst (that is, using the needle to draw fluid from the cyst) to remove it completely or relieve discomfort if the cyst is large and tender.

If the lesion cannot be felt from the surface of the skin, the doctor may use guidance for the FNA by using ultrasound images or pictures (see [Ultrasound](#)). This shows an image of the inside of your breast on a screen to allow the doctor to ensure the needle is going into the lesion. Alternatively, this can be done under stereotactic (mammography) guidance if the lesion has only shown up on a mammogram.

How do I prepare for a Breast FNA?

There is no need for special preparation before a Breast FNA. Breast FNA can be done immediately after you have had a medical examination and any imaging your doctor may have referred you for, such as a mammogram and/or ultrasound to find out the cause of the lesion.

Breast FNA can be uncomfortable and sometimes painful and you may wish to ask a friend or a relative to attend the appointment with you if you think you will need some support before or after the procedure.

Wear a comfortable two piece outfit, as you will need to have the upper body undressed for the Breast FNA.

What happens during a Breast FNA?

The doctor performing the breast FNA will decide whether it is best to use ultrasound or mammography images or pictures to locate the lesion and guide placement of the needle. If the doctor can feel the lesion it is said to be "palpable", and these are sometimes sampled without using imaging to guide the needle.

Ultrasound guidance

You will be lying on your back on the examination bed in the ultrasound room, the upper body undressed, with one arm above your head on the pillow in a comfortable position. The doctor will put a clear gel on your breast and the ultrasound transducer or probe (see [Ultrasound](#)) will be slowly moved across the breast to show and identify the lesion on the ultrasound screen. The doctor will clean your breast with an antiseptic liquid and place the needle through the skin and into the lesion guided by the ultrasound images.

Local anaesthetic on the skin area where the needle is inserted is sometimes given. If the doctor does not provide anaesthetic you can ask about this before the needle is inserted.

When the needle is inserted into the lesion, the doctor will make several small (less than 1 cm) forward and backward, gentle movements with the needle to collect cells or, if the lesion is a cyst, fluid may be collected. Two or three separate samples are usually taken in this way to ensure a good sample has been obtained.

Mammogram guidance

If the lesion is too small to feel and cannot be located with ultrasound, you may need mammography to find the lesion and help the radiologist direct the needle into the lesion to get a sample of tissue.

It is much more common for mammographic biopsies to be core biopsies (see [Breast Core Biopsy](#)) rather than FNA. The procedures are generally very similar.

You may be sitting up or lying face down for Breast FNA depending on the equipment that is used. After the needle is placed into the breast, the radiographer will take mammograms to check the correct positioning of the needle within the lesion before the sample is taken.

Are there any after effects of a Breast FNA?

Breast FNA can be uncomfortable and sometimes painful. Local anaesthetic is sometimes used and can be requested if needed. Any pain after FNA can be relieved with non-prescription analgesics like paracetamol. You should not take aspirin because this thins the blood and may increase bleeding and bruising.

Minimal bleeding or bruising can appear after the procedure, especially if you are taking anticoagulant medication (aspirin, warfarin or Plavix). Breast FNA does not leave a scar on the skin.

There is no significant risk of infection as a result of FNA. A small proportion of women feel faint during FNA but this generally passes quite quickly after the test has finished. A pneumothorax (perforation of the space around the lung by the biopsy needle with collapse of the lung) is extremely rare.

How long does a Breast FNA take?

Breast FNA is a quick test, which takes 10 to 20 seconds for each sample and this procedure may be repeated several times until the doctor is sure a good sample is collected. The examination and FNA procedure will generally take around 20 to 30 minutes for ultrasound guidance and 45-60 minutes for mammographic guidance.

What are the risks of a Breast FNA?

The risks of a Breast FNA are rare and minimal and can include:

- Minimal bleeding and bruising, especially for those on anticoagulation (warfarin, heparin), aspirin, or anti-platelet medication.
- Risk of infection is rare. Breast FNA is a clean and sterile procedure, which uses skin antiseptic and disposable one-use needles.
- Breast implant perforation can happen if the lesion is close to the implant but is a rare complication using ultrasound or stereotactic (mammography) guidance.
- Pneumothorax (perforation of the lung cover by the needle with lung collapse) is an extremely rare but serious complication that is more frequent if the lesion is deeply located in a small breast.
- If the lesion being biopsied is found to be cancer, there is a very small risk of displacement ("seeding" or implantation) of tumour cells along the tract or path of the needle as it is withdrawn from the breast. This is extremely rare.
- Breast FNA may not always provide a definitive diagnosis (or answer) about what the lesion in your breast is. In particular, it may not allow cancer to be definitely ruled out even if no cancer cells are found in the samples of material removed from your breast. The result of the FNA needs to be considered along with the results of other breast imaging and your doctor's examination findings.

Breast FNA is not 100% accurate. The results must always be interpreted by the doctors caring for you in the context of the findings of your breast imaging (mammogram and/or ultrasound), pathology results of the tissue or fluid sample and the findings of a medical examination. This is called the "triple test".

What are the benefits of a Breast FNA?

Breast FNA is a quick and simple procedure to perform to investigate a breast lesion.

There are few complications in having the test and few cases where the test is not appropriate due to a pre-existing medical or physical condition. Breast FNA can be used when other needle biopsy

procedures are not possible, for example, if you are using anticoagulant medication, have an allergy to anaesthetic, or have a breast implant.

Who does the Breast FNA?

Breast FNA should be done after careful medical examination and imaging tests such as mammogram or ultrasound as part of the "triple test" to ensure the correct diagnosis is made. Breast FNA is done by specialist doctors experienced in breast needle biopsy procedures.

Where is a Breast FNA done?

Breast FNA is an outpatient procedure. Image guided Breast FNA will be performed in a public or private hospital, radiology practice, a public or private specialist breast clinic, at a BreastScreen assessment clinic, or a surgeon or doctors' rooms equipped with ultrasound.

When can I expect the results of my Breast FNA?

Tests of the fluid or tissue sample will need to be done in a laboratory to confirm the diagnosis and are usually available within one or two days. These results, together with the results of medical and imaging examinations, are considered and interpreted and a report written for your referring doctor. Usually, you can obtain the final results of the Breast FNA from your own doctor within a week.

Useful websites about Breast FNA:

- A reference book: *Breast fine needle aspiration cytology and core biopsy: a guide for practice*, is available on-line on the National Breast and Ovarian Cancer Centre website: www.nbcc.org.au/resources/resource.php?code=FNA
